Therefore, the operations of the microprocessors used in the machines are not discussed they are explained in terms of from sensors to the input of the DC controller PCB and from the output of the DC controller PCB to the loads. The CPU of the reader unit interprets input signals and the signals from the host machine, and generates

signals used to drive such DC loads as motors and solenoids. The ADF controller PCB does not have a memory area, and the EEPROM of the reader controller PCB is used to store such data as service mode settings. It uses 2 motors for picking up and moving originals. As a result, the last original sensor PI8 generates the last original detection signal ENDS; when the last original moves past the original sensor PI9, the sensor generates the original absent signal EMPS to communicate to the host machine that the original being picked up is the last original. When the Start key is pressed, the original size is checked and communicated to the host machine in real time. The original width detection volume operates in conjunction with the slide guide, and the movement of the guide changes the resistance of the volume analog.

Appendix 5

5. Wiring Diagrams

Collision Warning System with Side Object Detection

The ADF controller checks the changes in the resistance through the original size signal VR to identify the length of the original in cross feed. Some paper sizes, however, are located appreciably near each other, possibly stopping the guide at the wrong position. The machine uses the length of feed with reference to the number of clock pulses from the feed motor M1 generated from when the read sensor PI3 goes on until when the sensor goes off. The read sensor I3 generates the last original detection signal ENDS for the ADF controller PCB. The stopper moves up in keeping with the movement of the pickup roller unit. The separation plate and the separation pad serve to prevent multiple feeding. In stream reading mode, the machine moves the original over the glass of the host machine for scanning. The host machine's scanner is held in position. The stopper moves up in keeping with the movement of the pickup unit; the separation pad and the separation plate are used to prevent multiple feeding that otherwise may occur at time of pickup. All this while, the separation roller drive shaft driven by way of the spring oneway clutch remains at rest at the upper limit of the pickup roller; the separation roller rotates by the friction against paper and by the work of the oneway clutch. As soon as reading ends, the image leading edge signal goes off, the locking solenoid SL1 goes on so that the delivery reversing roller gets locked in place, causing the paper to move to the delivery assembly.
